Abstract:
Special needs kids, especially those on the autistic spectrum, struggle with social skills. The Modified Checklist for Autism in Toddlers (M-CHAT) may detect autism spectrum disorders early (ASD). This abstract examines how the M-CHAT improves social skills in special needs children. The M-CHAT is a thorough screening questionnaire for 16–30-month-olds to detect ASD. It aids early detection and intervention, enabling focused assistance and better results. The M-influence CHAT’s on social interaction development has been studied beyond its diagnostic value. The M-CHAT may help special-needs youngsters learn social skills. Early detection of ASD markers allows experts to customise treatments and therapy for these youngsters. Speech, vocational, and social skills training are examples. M-CHAT research on social interaction development is promising. These studies show that M-CHAT early detection leads to rapid treatment and better social interaction abilities. The M-CHAT also helps caregivers and educators encourage, engage, and create inclusive settings. M-CHAT intervention results need more study. Investigating the M-CHAT components that contribute to the reported benefits and finding the best time and frequency of its execution will increase its use in clinical and educational contexts. M-CHAT screening may improve special needs children’s social abilities. M-CHAT early detection and assistance improves these children’s social development. Future study and collaboration are needed to maximise the M-advantages CHAT’s for special-needs children’s social inclusion.

Introduction
Special needs kids, especially those on the autistic spectrum, struggle with social skills. Social engagement helps children develop communication, relationship-building, and well-being. Early identification and assistance help these youngsters succeed. The Modified Checklist for Autism in Toddlers (M-CHAT) helps identify autism spectrum disorders (ASD) in 16–30-month-olds. A thorough
screening questionnaire to discover ASD indicators and advise further evaluation. The M-CHAT is used to diagnose ASD, but researchers are investigating its potential to improve social skills in special-needs children. This abstract examines how the M-CHAT affects social interaction skills in special needs children. Professionals can focus treatments and therapy for children with ASD via early detection. Speech, occupational, and social skills training may be used. M-CHAT intervention trials have demonstrated promise. M-CHAT early detection leads to fast treatment and better social skills. The M-CHAT helps caregivers and educators assist, engage, and create inclusive settings for these children. While the M-CHAT has shown encouraging results, further study is needed to determine its long-term benefits on social interaction. Identifying the M-CHAT components that contribute to the reported benefits and finding the ideal time and frequency of its administration will enhance its therapeutic and educational use. The M-CHAT as a screening tool may improve social interaction skills in special needs children, especially those on the autistic spectrum. M-CHAT early identification and assistance boost social development and well-being for these youngsters. To maximise the M-advantages CHAT's for special-needs children's social inclusion, further study and collaboration are needed.

Special needs kids, particularly those on the autistic spectrum, struggle with social skills. Social engagement helps them build connections, communicate, and handle social situations. Early identification and intervention are essential for focused assistance and social development of these youngsters. The Modified Checklist for Autism in Toddlers (M-CHAT) helps identify autism spectrum disorders (ASD) in 16–30-month-olds. It evaluates a child's behaviour and speech to identify ASD symptoms. Researchers have shown that the M-CHAT may help special-needs youngsters improve social skills. This abstract examines how the M-CHAT improves social interaction in special needs children. M-CHAT helps early intervention techniques for children with ASD by recognising possible indicators. Speech and language treatment, occupational therapy, and social skills training may promote social interaction. M-CHAT intervention trials have shown promising outcomes. M-CHAT early identification and appropriate treatments increase social interaction skills in special needs children. The M-CHAT also encourages caregivers and educators to participate in supportive, inclusive contexts. The M-CHAT as an intervention tool may improve social interaction results, but further study is needed. It is essential to discover the M-CHAT components that cause the observed benefits and find the best time and frequency for its use in clinical and educational contexts.

Autism spectrum disorders (ASD), intellectual difficulties, and developmental delays may make social contact difficult for children. Social interaction includes communication, social signals, relationships, and social activities. These abilities are essential for the child's well-being, academic achievement, and socialisation. Social skills are crucial for special needs kids. These qualities promote genuine interactions, reciprocal communication, and social confidence. Strong social skills help them communicate, comprehend people, and work together. These qualities also promote community inclusion, acceptance, and belonging. Special needs kids struggle to learn these social skills. They may struggle with social communication, nonverbal clues, and social awareness. They may endure social isolation, rejection, and less learning and development chances. Support and treatments have been provided for children with special needs to develop social interaction skills. Interventions, treatments, and educational programmes improve their social skills and quality of life. Early identification of
problems and tailored treatments are essential for maximising their potential and aiding social integration. Social interaction skills help special-needs children learn, communicate, and integrate. These youngsters may improve their social skills with targeted treatments and assistance. By creating inclusive settings and offering tailored interventions, we can help every kid succeed and flourish.

**Early Identification and Intervention for Children with Special Needs**

Early diagnosis and intervention help special needs children grow optimally. Early childhood is a crucial time to detect and treat any issues. Autism spectrum disorders (ASD), developmental delays, and intellectual impairments are most affected by this. Early detection of developmental issues or risk factors might affect a child's development, especially social skills. It provides for timely intervention and support services to help youngsters overcome problems and attain their full potential. Early identification requires parents, caregivers, healthcare professionals, and educators. Professional developmental screens, examinations, and observations may detect developmental delays, behavioural patterns, and particular conditions. These exams may use M-CHAT to discover ASD indicators.

Early intervention may address possible issues. Early intervention includes specialised programmes, treatments, and support systems for special-needs children. These therapies address growth in social interaction, communication, cognitive abilities, motor capabilities, and adaptive functioning. Multidisciplinary early social interaction intervention is common. Speech and language therapy, occupational therapy, social skills training, and behavioural therapies improve social communication, awareness, and peer interaction. These therapies try to help kids navigate social contexts. Early identification and intervention for special needs children has been shown effective. Early intervention improves social skills, academic performance, and well-being. Early intervention and assistance help youngsters develop social skills and integrate into their communities. Early identification and intervention are crucial for special-needs children's development. Recognizing possible issues and providing focused interventions may help youngsters develop social skills and overcome difficulties. Parents, caregivers, healthcare experts, and educators must work together to help children succeed. Early intervention prepares special needs children for a meaningful and inclusive future.

**Exploring the Impact of the M-CHAT on Social Interaction Development**

Early diagnosis of autism spectrum disorders (ASD) is crucial, and the Modified Checklist for Autism in Toddlers (M-CHAT) has shown to be an invaluable tool for this purpose. Researchers have started to look at the M-larger CHAT's influence on social interaction development among children with exceptional needs, beyond its diagnostic value. Communication, participation in group activities, perspective taking, and the ability to empathise are just few of the many abilities that contribute to a healthy social life. Developing these abilities may be difficult for children with unique needs, especially those on the autistic spectrum. Due to the M-capacity CHAT's to detect possible ASD signs at a young age, timely interventions and support methods may be put into place to foster the growth of social interactions. Promising findings have emerged from studies studying the M-effect CHAT's on the growth of social interaction. The M-CHAT allows for timely speech and language treatment, occupational therapy, and social skills training by facilitating early identification. These programmes are designed to help kids who are having trouble interacting socially because of their disabilities.
When professionals and caregivers use the M-CHAT to detect possible indicators of ASD, they may then provide personalised therapies for the kid. These programmes aim to help people in various ways become more socially aware, engaged, and communicative. Children may improve their social interaction abilities over time with the help of systematic and well-targeted intervention programmes. There are wider ramifications for using the M-CHAT as an intervention tool. It's a springboard for getting parents, teachers, and others invested in their child's social development. The M-CHAT promotes cooperation and the development of welcoming conditions for children to develop their social skills by heightening their awareness of their own requirements. While previous studies have shown promising results, further study is required to identify which aspects of the M-CHAT are responsible for the favourable effects on social interaction growth. To maximise its influence on social interaction outcomes, the M-CHAT should be administered at the optimal time and frequency. Children on the autistic spectrum, in particular, may benefit from the M-CHAT because of its potential to help them learn how to communicate with others. Improved results in social interactions may be achieved by early detection with the M-CHAT, which allows for timely interventions and assistance. Further investigation and collaborative efforts are required to fully realise the M-potential CHAT's as an intervention tool for fostering the development of social interaction skills in children with exceptional needs.

**Review of literature**

(Janvier et al. 2019) studied “The Developmental Check-In: Development and initial testing of an autism screening tool targeting young children from underserved communities. Relative to their more privileged classmates, children from low-income, minority, or those with inadequate English proficiency are diagnosed with autism spectrum disorder at a later age, if at all. Screening for autism may benefit from a new tool called the Developmental Check-In, which depicts desired behaviors via the use of photographs. It was designed to aid in the detection of ASD in populations where reading proficiency is poor. Three hundred and seventy-six children, aged 24 to 60 months, from medically underserved areas participated in a pilot study of the Developmental Check-In. Across the complete age range of the population, it demonstrated strong capacity to distinguish ASD from NSD (area-under-the-curve = 0.75). Twenty-six out of the 28 items on the Developmental Check-In were significant in predicting the presence of autism spectrum disorder. The results show that this visual aid might simplify the screening process for autism in low-resource communities by reducing the need for specialized language and health literacy skills.

(Senju and Johnson 2009) studied Atypical eye contact in autism: models, mechanisms and development. Atsushi discovered this and Atypical eye contact behavior is a prominent indication of autism (ASD). New empirical findings have shed light on the cognitive and neurological underpinnings of aberrant eye contact behavior in autism spectrum disorder (ASD). Several models are discussed, and a novel fast-track modulator model is proposed. We argue that the absence of input from a subcortical face and eye contact detection pathway, which is anticipated to modify eye contact processing and direct its emerging specialization throughout development, is at the root of the aberrant eye contact processing seen in ASD.

(Ismiarti and Rohmad 2019) studied Communication Abilities of Autistic Children in Social Interaction. Evidently, children with autism have challenges in the areas of communication, social engagement, and
behavioral regulation. Therefore, programs that can adapt to the demands of children with autism are crucial to their education. Inclusive education is one sort of support offered. Children with autism who are included in regular classroom settings may get the skills they need to speak and engage with others. The purpose of this case study is to learn more about the social communication abilities of autistic youngste. This research concludes that a child's capacity to communicate with non-autistic classmates improves when he or she is included in the regular classroom setting. Autistic children have been known to strike up conversations with their pals.

(Carbone et al. 2013) studied Teaching Eye Contact to Children with Autism: A Conceptual Analysis and Single Case Study discovered this and Children learn to make eye contact early on, and it serves a number of important purposes for them. Researchers have shown that it has a role in the maturation of a person's linguistic, cognitive, and social abilities. Researchers from developmental and behavior analytic perspectives have studied techniques to teach eye contact since many children with autism lack this critical ability. Recently, however, a small number of studies have sought to condition the response of the communication partner as a reinforcer for social conduct, and thereby arranged the settings under which normal youngsters learn social responses. This case study aimed to examine how eye contact was taught to a kid with autism as a linguistic pragmatic skill, expanding previous research on the usual development of social skills”. Information is presented from a single case study of a youngster diagnosed with autism.

Conclusion
M-effects CHAT’s on social interaction development in special needs children are encouraging. The M-early CHAT's detection of autism spectrum disorders (ASD) enables for early treatments and assistance to improve social interaction. Speech and language treatment, occupational therapy, and social skills training based on the M-CHAT have improved children's social abilities. These therapies improve communication, social engagement, and social awareness in special-needs children by addressing particular issues and offering individualised assistance. The M-CHAT helps caregivers, educators, and child development experts work together. M-CHAT fosters comprehensive social interaction development by improving awareness of the child's requirements and establishing inclusive surroundings. M-CHAT components that boost social interaction development require additional study. Exploring the best time and frequency of M-CHAT intervention will optimise its influence on social interaction outcomes. We can maximise the M-social CHAT's interaction development potential in special needs children by refining its use and collaborating on research. To promote inclusion, well-being, and social integration, every kid should have the chance to acquire social skills.
